condyles. A 10% or more difference in the radionuclide uptake between the left and right condyles with increased uptake ipsilateral to the CH is considered to be evidence of active, growing CH (1–3).

Normally, the condyles are nearly symmetric and CT is a useful tool to measure and evaluate condylar dimensions (5). Degenerative or inflammatory arthropathies of TMJs may complicate evaluation of comparative uptake, but these conditions are more common and more severe on the side contralateral to the CH.

CONCLUSION

This case suggests that bone scan SPECT/CT provides an accurate means for the assessment of growth activity and detailed underlying anatomic information in a patient with CH. These are helpful not only for diagnosis but also for the choice of an appropriate treatment. Degenerative arthropathies of TMJs may complicate evaluation of comparative uptake, but these conditions are more common and more severe on the side contralateral to the CH.

**Erratum**

In Appendix A of the article “SNMMI and EANM Practice Guideline for Meckel Diverticulum Scintigraphy 2.0,” by Spottswood et al. (J Nucl Med Technol. 2014;42:163–169), the pretreatment oral dose of ranitidine in adults referred for a Meckel scan was incorrectly stated to be 150 mg/kg. The correct dose is 150 mg. The authors regret the error.
